Preface

This document describes the functionality provided by the Group Orchestrator plugin.

See the **Deployit Reference Manual** for background information on Deployit and deployment concepts.

Description

Orchestrators in Deployit define the strategies used to combine the *steps* for the individual component changes into an overall deployment workflow. The *default* orchestrator, for instance, “interleaves” all individual component changes by running all steps of a given order for all components.

The *group* orchestrator groups steps based on the *deployment group* synthetic property on a container. All component changes for a given container are put in the same group and all groups are combined into a single deployment workflow. This allows fine-grained control over which containers are deployed to together.

Features

- Assign containers to a *deployment group*
- Orchestrate a deployment so all steps dealing with containers in the same *deployment group* are grouped together

Requirements

The plugin requires:

- **Deployit:** version 3.7+
